# Package 'SqlRender'

May 28, 2018

Type Package

Title Rendering Parameterized SQL and Translation to Dialects	
Version 1.5.0	
<b>Date</b> 2018-05-28	
Maintainer Martijn Schuemie <schuemie@ohdsi.org></schuemie@ohdsi.org>	
Description A rendering tool for parameterized SQL that also translates into different SQL dialects. These dialects include 'Microsoft Sql Server', 'Oracle', 'PostgreSql', 'Amazon RedShift', 'Apache Impala', 'IBM Netezza', 'Google BigQuery', and 'M crosoft PDW'.	i-

# **Description**

Convert a camel case string to snake case

## Usage

camelCaseToSnakeCase(string)

#### **Arguments**

string The string to be converted

#### Value

A string

# **Examples**

```
camelCaseToSnakeCase("exposureConceptId1")
# > 'exposure_concept_id_1'
```

createRWrapperForSql Create an R wrapper for SQL

# Description

createRWrapperForSql creates an R wrapper for a parameterized SQL file. The created R script file will contain a single function, that executes the SQL, and accepts the same parameters as specified in the SQL.

## Usage

```
createRWrapperForSql(sqlFilename, rFilename, packageName,
    createRoxygenTemplate = TRUE)
```

# Arguments

sqlFilename The SQL file.

rFilename The name of the R file to be generated. Defaults to the name of the SQL file

with the extention reset to R.

packageName The name of the package that will contains the SQL file.

 ${\tt createRoxygenTemplate}$ 

If true, a template of Roxygen comments will be added.

#### **Details**

This function reads the declarations of defaults in the parameterized SQL file, and creates an R function that exposes the parameters. It uses the loadRenderTranslateSql function, and assumes the SQL will be used inside a package. To use inside a package, the SQL file should be placed in the inst/sql/sql\_server folder of the package.

#### **Examples**

```
## Not run:
# This will create a file called CohortMethod.R:
createRWrapperForSql("CohortMethod.sql", packageName = "CohortMethod")
## End(Not run)
```

launchSqlRenderDeveloper

Launch the SqlRender Developer Shiny app

#### **Description**

Launch the SqlRender Developer Shiny app

## Usage

launchSqlRenderDeveloper(launch.browser = TRUE)

## **Arguments**

launch.browser Should the app be launched in your default browser, or in a Shiny window. Note: copying to clipboard will not work in a Shiny window.

# **Details**

Launches a Shiny app that allows the user to develop SQL and see how it translates to the supported dialects.

loadRenderTranslateSql

Load, render, and translate a SQL file in a package

# **Description**

loadRenderTranslateSql Loads a SQL file contained in a package, renders it and translates it to the specified dialect

## Usage

```
loadRenderTranslateSql(sqlFilename, packageName, dbms = "sql server", ...,
  oracleTempSchema = NULL, warnOnMissingParameters = TRUE)
```

4 readSql

## **Arguments**

sqlFilename The source SQL file

packageName The name of the package that contains the SQL file

dbms The target dialect. Currently 'sql server', 'oracle', 'postgres', and 'redshift' are

supported

... Parameter values used for renderSql

oracleTempSchema

A schema that can be used to create temp tables in when using Oracle.

 ${\it warn On Missing Parameters}$ 

Should a warning be raised when parameters provided to this function do not appear in the parameterized SQL that is being rendered? By default, this is

TRUE.

#### **Details**

This function looks for a SQL file with the specified name in the inst/sql/<dbms> folder of the specified package. If it doesn't find it in that folder, it will try and load the file from the inst/sql/sql\_server folder and use the translateSql function to translate it to the requested dialect. It will subsequently call the renderSql function with any of the additional specified parameters.

#### Value

Returns a string containing the rendered SQL.

# **Examples**

readSql

Reads a SQL file

# Description

```
readSql loads SQL from a file
```

#### Usage

```
readSql(sourceFile)
```

# Arguments

sourceFile The source SQL file

renderSql 5

#### **Details**

```
readSql loads SQL from a file
```

#### Value

Returns a string containing the SQL.

#### **Examples**

```
## Not run:
readSql("myParamStatement.sql")
## End(Not run)
```

renderSql

renderSql

#### **Description**

renderSql Renders SQL code based on parameterized SQL and parameter values.

## Usage

```
renderSql(sql = "", warnOnMissingParameters = TRUE, ...)
```

# Arguments

 $\begin{array}{c} \text{sql} & \text{The parameterized SQL} \\ \text{warnOnMissingParameters} \end{array}$ 

Should a warning be raised when parameters provided to this function do not appear in the parameterized SQL that is being rendered? By default, this is

TRUE.

... Parameter values

# **Details**

This function takes parameterized SQL and a list of parameter values and renders the SQL that can be send to the server. Parameterization syntax:

@parameterName Parameters are indicated using a @ prefix, and are replaced with the actual values provided in the renderSql call.

**{DEFAULT @parameterName = parameterValue}** Default values for parameters can be defined using curly and the DEFAULT keyword.

{if}?{then}:{else} The if-then-else pattern is used to turn on or off blocks of SQL code.

#### Value

A list containing the following elements:

```
parameterizedSql The original parameterized SQL code
sql The rendered sql
```

6 renderSqlFile

#### **Examples**

```
renderSql("SELECT * FROM @a;", a = "myTable")
renderSql("SELECT * FROM @a {@b}?{WHERE x = 1};", a = "myTable", b = "true")
renderSql("SELECT * FROM @a {@b == ''}?{WHERE x = 1}: {ORDER BY x};", a = "myTable", b = "true")
renderSql("SELECT * FROM @a {@b != ''}?{WHERE @b = 1};", a = "myTable", b = "y")
renderSql("SELECT * FROM @a {1 IN (@c)}?{WHERE @b = 1};",
          a = "myTable",
         b = "y",
          c = c(1, 2, 3, 4))
renderSql("{DEFAULT @b = \"someField\"}SELECT * FROM @a {@b != ''}?{WHERE @b = 1};",
          a = "myTable")
renderSql("SELECT \star FROM @a {@a == 'myTable' & @b != 'x'}?{WHERE @b = 1};",
          a = "myTable",
          b = "y"
renderSql(sql = "SELECT * FROM @a;",
          warnOnMissingParameters = FALSE,
          a = "myTable",
          b = "missingParameter")
```

renderSqlFile

Render a SQL file

# Description

renderSqlFile Renders SQL code in a file based on parameterized SQL and parameter values, and writes it to another file.

# Usage

```
renderSqlFile(sourceFile, targetFile, warnOnMissingParameters = TRUE, ...)
```

## **Arguments**

```
sourceFile The source SQL file targetFile The target SQL file warnOnMissingParameters
```

Should a warning be raised when parameters provided to this function do not appear in the parameterized SQL that is being rendered? By default, this is TRUE.

... Parameter values

#### **Details**

This function takes parameterized SQL and a list of parameter values and renders the SQL that can be send to the server. Parameterization syntax:

@parameterName Parameters are indicated using a @ prefix, and are replaced with the actual values provided in the renderSql call.

**{DEFAULT @parameterName = parameterValue}** Default values for parameters can be defined using curly and the DEFAULT keyword.

{if}?{then}:{else} The if-then-else pattern is used to turn on or off blocks of SQL code.

snakeCaseToCamelCase 7

## **Examples**

```
## Not run:
renderSqlFile("myParamStatement.sql", "myRenderedStatement.sql", a = "myTable")
## End(Not run)
```

snakeCaseToCamelCase

Convert a snake case string to camel case

# **Description**

Convert a snake case string to camel case

# Usage

```
snakeCaseToCamelCase(string)
```

# Arguments

string

The string to be converted

## Value

A string

# Examples

```
snakeCaseToCamelCase("exposure_concept_id_1")
# > 'exposureConceptId1'
```

splitSql

splitSql

# **Description**

splitSql splits a string containing multiple SQL statements into a vector of SQL statements

# Usage

```
splitSql(sql)
```

# Arguments

sql

The SQL string to split into separate statements

# **Details**

This function is needed because some DBMSs (like ORACLE) do not accepts multiple SQL statements being sent as one execution.

8 translateSql

#### Value

A vector of strings, one for each SQL statement

## **Examples**

```
splitSql("SELECT * INTO a FROM b; USE x; DROP TABLE c;")
```

SqlRender

SqlRender

## **Description**

SqlRender

translateSql

translateSql

# **Description**

translateSql translates SQL from one dialect to another

# Usage

```
translateSql(sql = "", targetDialect, oracleTempSchema = NULL,
   sourceDialect)
```

# **Arguments**

sql The SQL to be translated

targetDialect The target dialect. Currently "oracle", "postgresql", "pdw", "impala", "netezza",

"bigquery", and "redshift" are supported

oracleTempSchema

A schema that can be used to create temp tables in when using Oracle or Impala.

sourceDialect Deprecated: The source dialect. Currently, only "sql server" for Microsoft SQL

Server is supported

## **Details**

This function takes SQL in one dialect and translates it into another. It uses simple pattern replacement, so its functionality is limited.

# Value

A list containing the following elements:

```
originalSql The original parameterized SQL code
sql The translated SQL
```

translateSqlFile 9

## **Examples**

```
translateSql("USE my_schema;", targetDialect = "oracle")
```

translateSqlFile

Translate a SQL file

## **Description**

This function takes SQL and translates it to a different dialect.

## Usage

```
translateSqlFile(sourceFile, targetFile, sourceDialect, targetDialect,
  oracleTempSchema = NULL)
```

# Arguments

sourceFile The source SQL file

targetFile The target SQL file

sourceDialect Deprecated: The source dialect. Currently, only 'sql server' for Microsoft SQL Server is supported

targetDialect The target dialect. Currently 'oracle', 'postgresql', and 'redshift' are supported oracleTempSchema

A schema that can be used to create temp tables in when using Oracle.

# **Details**

This function takes SQL and translates it to a different dialect.

## **Examples**

10 writeSql

writeSql

Write SQL to a SQL (text) file

# Description

```
writeSql writes SQL to a file
```

# Usage

```
writeSql(sql, targetFile)
```

# **Arguments**

 $\begin{array}{ll} \text{sql} & \text{A string containing the sql} \\ \text{targetFile} & \text{The target SQL file} \end{array}$ 

# **Details**

```
writeSql writes SQL to a file
```

# **Examples**

```
## Not run:
sql <- "SELECT * FROM @table_name"
writeSql(sql, "myParamStatement.sql")
## End(Not run)</pre>
```
